

# TW-009 TEAM LEAD VERSION (Sprint-5 Week-2)

---

CLARUSWAY  
WAY TO REINVENT YOURSELF

## Meeting Agenda

---

- ▶ Icebreaking
- ▶ Questions
- ▶ Interview Questions
- ▶ Coding Challenge
- ▶ Video of the week
- ▶ Retro meeting
- ▶ Case study / project

# Teamwork Schedule

---

## Ice-breaking

5m

- Personal Questions (Study Environment, Kids etc.)
- Any challenges (Classes, Coding, studying, etc.)
- Ask how they're studying, give personal advice.
- Remind that practice makes perfect.

## Team work

5m

- Ask what exactly each student does for the team, if they know each other, if they care for each other, if they follow and talk with each other etc.

## Ask Questions

15m

### 1. When might you use `React.PureComponent`?

- A. when you do not want your component to have props
- B. when you have sibling components that need to be compared
- C. when you want a default implementation of `shouldComponentUpdate()`
- D. when you do not want your component to have state

Answer: C

### 2. You have written the following code but nothing is rendering. How do you fix this problem?

```
const Heading = () => {  
  <h1>Hello!</h1>;  
};
```

- A. Add a render function.
- B. Change the curly braces to parentheses or add a return statement before the `h1` tag.
- C. Move the `h1` to another component.
- D. Surround the `h1` in a `div`.

Answer: B

### 3. Which option is correct for State vs Props

- A. Props is something that the parent doesn't need and decide to throw around among other parents; State is the parent's favorite child and something the component wants to nurture.
- B. Props is a copy of real DOM; State is the definition of the real DOM.
- C. Props get passed to the component using naming conventions, like a function parameter; State is managed within the component and holds some information that may change over the lifetime of the component.
- D. Prop is managed within the component and holds some information that may change over the lifetime of the component; State gets passed to the component, like a function parameter

Answer: C

### 4. What package contains the render() function that renders a React element tree to the DOM?

- A. React
- B. ReactDOM
- C. Render
- D. DOM

Answer: B

### 5. Which of the following click event handlers will allow you to pass the name of the person to be hugged?

```
class Huggable extends React.Component {  
  hug(id) {  
    console.log("hugging " + id);  
  }  
  
  render() {  
    let name = "kittteh";  
    let button = // Missing Code  
    return button;  
  }  
}
```

- A. `<button onClick={{name} => this.hug(name)}>Hug Button</button>`
- B. `<button onClick={this.hug(e, name)}>Hug Button</button>`
- C. `<button onClick={(e) => hug(e, name)}>Hug Button</button>`
- D. `<button onClick={(e) => this.hug(name,e)}>Hug Button</button>`

Answer: D

**6. Which answer best describes a function component?**

- A.** A function component is required to create a React component.
- B.** A function component accepts a single props object and returns a React element.
- C.** A function component is the only way to create a component.
- D.** A function component is the same as a class component.

Answer: D

**7. What is the name of the tool used to take JSX and turn it into createElement calls?**

- A.** JSX Editor
- B.** ReactDOM
- C.** Browser Buddy
- D.** Babel

Answer: D

**8. If you see the following import in a file, what is being used for state management in the component?**

```
import React, {useState} from 'react';
```

- A.** React Hooks
- B.** stateful components
- C.** math
- D.** class components

Answer: A

**9. If you created a component called Dish and rendered it to the DOM, what type of element would be rendered?**

```
function Dish() {  
  return <h1> Mac and Cheese</h1>;  
}  
  
ReactDOM.render(  
  <Dish />  
  document.getElementById('root')  
)
```

- A. div
- B. section
- C. component
- D. h1

Answer: D

**10. Which of the following lifecycle methods does not get triggered on the component's initial render?**

- A. componentWillMount()
- B. componentWillReceiveProps()
- C. render()
- D. componentDidMount()

Answer: B

**11. What does this React element look like given the following function?**

```
React.createElement(  
  "h1",  
  null,  
  "What's happening?"  
);
```

A.

```
<h1 props={null}>What's happening?</h1>
```

B.

```
<h1 id="component">What's happening?</h1>
```

C.

```
<h1>What's happening?</h1>
```

**D.**

```
<h1 id="element">What's happening?</h1>
```

*Answer: C*

## Interview Questions

**15m**

### 1. What are controlled components?

Answer: In HTML, form elements such as "input", "textarea", and "select" typically maintain their own state and update it based on user input. When a user submits a form the values from the aforementioned elements are sent with the form. With React it works differently. The component containing the form will keep track of the value of the input in its state and will re-render the component each time the callback function e.g. onChange is fired as the state will be updated. A form element whose value is controlled by React in this way is called a "controlled component". With a controlled component, every state mutation will have an associated handler function. This makes it straightforward to modify or validate user input.

### 2. What is a higher order component?

Answer: A higher-order component (HOC) is an advanced technique in React for reusing component logic. HOCs are not part of the React API. They are a pattern that emerges from React's compositional nature. A higher-order component is a function that takes a component and returns a new component. HOCs allow you to reuse code, logic and bootstrap abstraction. HOCs are common in third-party React libraries. The most common is probably Redux's connect function. Beyond simply sharing utility libraries and simple composition, HOCs are the best way to share behavior between React Components. If you find yourself writing a lot of code in different places that does the same thing, you may be able to refactor that code into a reusable HOC.

### 3. How Virtual-DOM is more efficient than Dirty checking?

Answer: In React, each of our components have a state. This state is like an observable. Essentially, React knows when to re-render the scene because it is able to observe when this data changes. Dirty checking is slower than observables because we must poll the data at a regular interval and check all of the values in the data structure recursively. By comparison, setting a value on the state will signal to a listener that some state has changed, so React can simply listen for change events on the state and queue up re-rendering. The virtual DOM is used for efficient re-rendering of the DOM. This isn't really related to dirty checking your data. We could re-render using a virtual DOM with or without dirty checking. In fact, the diff algorithm is a dirty checker itself. We aim to re-render the virtual tree only when the state changes. So using an observable to check if the state has changed is an efficient way to prevent unnecessary re-renders, which would cause lots of unnecessary tree diffs. If nothing has changed, we do nothing.

## Coding Challenge

20m

- [Coding Challenge: Image Gallery \(R-01\)](#)
- 
- 

## Coffee Break

10m

## Video of the Week

5m

- [What Is React \(React js\) & Why Is It So Popular?](#)

## Retro Meeting on a personal and team level

5m

Ask the questions below:

- What went well?
- What went wrong?
- What is the improvement areas?

## Case study/Project

15m

**Case study should be explained to the students during the weekly meeting and has to be completed in one week by the students. Students should work in small teams to complete the case study.**

- [Tour Places \(RP-01\)](#)

## Closing

5m

-Next week's plan

-QA Session

---
